

## 5.7 Accessing the Standard CGI Variables

If you come to servlets with a background in traditional Common Gateway Interface (CGI) programming, you are probably used to the idea of "CGI variables." These are a somewhat eclectic collection of information about the current request. Some are based on the HTTP request line and headers (e.g., form data), others are derived from the socket itself (e.g., the name and IP address of the requesting host), and still others are taken from server installation parameters (e.g., the mapping of URLs to actual paths).

Although it probably makes more sense to think of different sources of data (request data, server information, etc.) as distinct, experienced CGI programmers may find it useful to see the servlet equivalent of each of the CGI variables. If you don't have a background in traditional CGI, first, count your blessings; servlets are easier to use, more flexible, and more efficient than standard CGI. Second, just skim this section, noting the parts not directly related to the incoming HTTP request. In particular, observe that you can use `getServletContext().getRealPath` to map a URI (the part of the URL that comes after the host and port) to an actual path and that you can use `request.getRemoteHost` and `request.getRemoteAddress` to get the name and IP address of the client.

### Servlet Equivalent of CGI Variables

For each standard CGI variable, this subsection summarizes its purpose and the means of accessing it from a servlet. Assume `request` is the `HttpServletRequest` supplied to the `doGet` and `doPost` methods.

#### AUTH\_TYPE

If an `Authorization` header was supplied, this variable gives the scheme specified (`basic` or `digest`). Access it with `request.getAuthType()`

#### CONTENT\_LENGTH

For `POST` requests only, this variable stores the number of bytes of data sent, as given by the `Content-Length` request header. Technically, since the `CONTENT_LENGTH` CGI variable is a string, the servlet equivalent is `String.valueOf(request.getContentLength())` or `request.getHeader("Content-Length")`. You'll probably want to just call `request.getContentLength()`, which returns an `int`.

#### CONTENT\_TYPE

`CONTENT_TYPE` designates the MIME type of attached data, if specified. See [Table 7.1](#) in [Section 7.2](#) (Understanding HTTP 1.1 Response Headers) for the names and meanings of the common MIME types. Access `CONTENT_TYPE` with `request.getContentType()`.

#### DOCUMENT\_ROOT

The `DOCUMENT_ROOT` variable specifies the real directory corresponding to the URL `http://host/`. Access it with `getServletContext().getRealPath("/")`. Also, you can use `getServletContext().getRealPath` to map an arbitrary URI (i.e., URL suffix that comes after the hostname and port) to an actual path on the local machine.

## HTTP\_XXX\_YYY

Variables of the form `HTTP_HEADER_NAME` are how CGI programs access arbitrary HTTP request headers. The `Cookie` header becomes `HTTP_COOKIE`, `User-Agent` becomes `HTTP_USER_AGENT`, `Referer` becomes `HTTP_REFERER`, and so forth. Servlets should just use `request.getHeader` or one of the shortcut methods described in [Section 5.1](#) (Reading Request Headers).

## PATH\_INFO

This variable supplies any path information attached to the URL after the address of the servlet but before the query data. For example, with

`http://host/servlet/coreservlets.SomeServlet/foo/bar?baz=quux`, the path information is `/foo/bar`. Since servlets, unlike standard CGI programs, can talk directly to the server, they don't need to treat path information specially. Path information could be sent as part of the regular form data and then translated by `getServletContext().getRealPath`. Access the value of `PATH_INFO` by using `request.getPathInfo()`.

## PATH\_TRANSLATED

`PATH_TRANSLATED` gives the path information mapped to a real path on the server. Again, with servlets there is no need to have a special case for path information, since a servlet can call `getServletContext().getRealPath` to translate partial URLs into real paths. This translation is not possible with standard CGI because the CGI program runs entirely separately from the server. Access this variable by means of `request.getPathTranslated()`.

## QUERY\_STRING

For `GET` requests, this variable gives the attached data as a single string with values still URL-encoded. You rarely want the raw data in servlets; instead, use `request.getParameter` to access individual parameters, as described in [Section 5.1](#) (Reading Request Headers). However, if you do want the raw data, you can get it with `request.getQueryString()`.

## REMOTE\_ADDR

This variable designates the IP address of the client that made the request, as a `String` (e.g., `"198.137.241.30"`). Access it by calling `request.getRemoteAddr()`.

## REMOTE\_HOST

`REMOTE_HOST` indicates the fully qualified domain name (e.g., `whitehouse.gov`) of the client that made the request. The IP address is returned if the domain name cannot be determined. You can access this variable with `request.getRemoteHost()`.

## REMOTE\_USER

If an `Authorization` header was supplied and decoded by the server itself, the `REMOTE_USER` variable gives the user part, which is useful for session tracking in protected sites. Access it with `request.getRemoteUser()`. For decoding `Authorization` information directly in servlets, see the chapters on Web application security in Volume 2 of this book.

## REQUEST\_METHOD

This variable stipulates the HTTP request type, which is usually `GET` or `POST` but is occasionally `HEAD`, `PUT`, `DELETE`, `OPTIONS`, or `TRACE`. Servlets rarely need to look up `REQUEST_METHOD` explicitly, since each of the request types is typically handled by a different servlet method (`doGet`, `doPost`, etc.). An exception is `HEAD`, which is handled automatically by the `service` method returning whatever headers and status codes the `doGet` method would use. Access this variable by means of `request.getMethod()`.

## SCRIPT\_NAME

This variable specifies the path to the servlet, relative to the server's root directory. It can be accessed through `request.getServletPath()`.

## SERVER\_NAME

`SERVER_NAME` gives the host name of the server machine. It can be accessed by means of `request.getServerName()`.

## SERVER\_PORT

This variable stores the port the server is listening on. Technically, the servlet equivalent is `String.valueOf(request.getServerPort())`, which returns a `String`. You'll usually just want `request.getServerPort()`, which returns an `int`.

## SERVER\_PROTOCOL

The `SERVER_PROTOCOL` variable indicates the protocol name and version used in the request line (e.g., `HTTP/1.0` or `HTTP/1.1`). Access it by calling `request.getProtocol()`.

## SERVER\_SOFTWARE

This variable gives identifying information about the Web server. Access it by means of `getServletContext().getServerInfo()`.

## A Servlet That Shows the CGI Variables

[Listing 5.7](#) presents a servlet that creates a table showing the values of all the CGI variables other than `HTTP_XXX_YYY`, which are just the HTTP request headers described in [Section 5.3](#). [Figure 5-10](#) shows the result for a typical request.

### Listing 5.7 ShowCGIVariables.java

```
package coreservlets;

import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.util.*;

/** Creates a table showing the current value of each
 *  of the standard CGI variables.
 */

public class ShowCGIVariables extends HttpServlet {
```

```

public void doGet(HttpServletRequest request,
                  HttpServletResponse response)
    throws ServletException, IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    String[][] variables =
        { { "AUTH_TYPE", request.getAuthType() },
          { "CONTENT_LENGTH",
            String.valueOf(request.getContentLength()) },
          { "CONTENT_TYPE", request.getContentType() },
          { "DOCUMENT_ROOT",
            getServletContext().getRealPath("/") },
          { "PATH_INFO", request.getPathInfo() },
          { "PATH_TRANSLATED", request.getPathTranslated() },
          { "QUERY_STRING", request.getQueryString() },
          { "REMOTE_ADDR", request.getRemoteAddr() },
          { "REMOTE_HOST", request.getRemoteHost() },
          { "REMOTE_USER", request.getRemoteUser() },
          { "REQUEST_METHOD", request.getMethod() },
          { "SCRIPT_NAME", request.getServletPath() },
          { "SERVER_NAME", request.getServerName() },
          { "SERVER_PORT",
            String.valueOf(request.getServerPort()) },
          { "SERVER_PROTOCOL", request.getProtocol() },
          { "SERVER_SOFTWARE",
            getServletContext().getServerInfo() }
        };
    String title = "Servlet Example: Showing CGI Variables";
    String docType =
        "<!DOCTYPE HTML PUBLIC \"-//W3C//DTD HTML 4.0 \" +
        \"Transitional//EN\">\n";
    out.println(docType +
        "<HTML>\n" +
        "<HEAD><TITLE>" + title + "</TITLE></HEAD>\n" +
        "<BODY BGCOLOR=\"#FDF5E6\">\n" +
        "<CENTER>\n" +
        "<H1>" + title + "</H1>\n" +
        "<TABLE BORDER=1>\n" +
        "  <TR BGCOLOR=\"#FFAD00\">\n" +
        "    <TH>CGI Variable Name<TH>Value");
    for(int i=0; i<variables.length; i++) {
        String varName = variables[i][0];
        String varValue = variables[i][1];
        if (varValue == null)
            varValue = "<I>Not specified</I>";
        out.println("  <TR><TD>" + varName + "<TD>" + varValue);
    }
    out.println("</TABLE></CENTER></BODY></HTML>");
}

/** POST and GET requests handled identically. */

public void doPost(HttpServletRequest request,
                  HttpServletResponse response)
    throws ServletException, IOException {
    doGet(request, response);
}
}

```
