

MIDTERM EXAMINATION – CLASS

Student Name: _____ Student ID: _____

Date: April 2021

Duration: 90 minutes

SUBJECT: PHYSICS 3

Chair of Department of Physics:

Signature:

Full name: Phan Bảo Ngọc

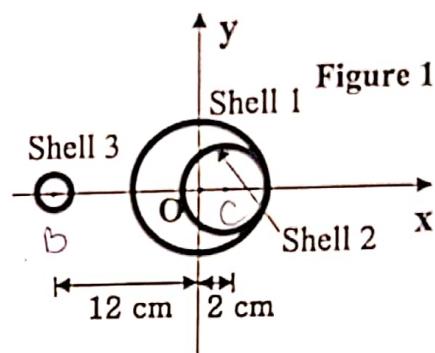

Lecturer: Phan Bảo Ngọc

Signature:

Full name:

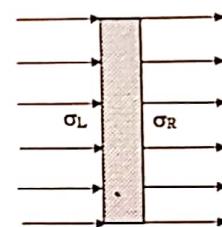

INSTRUCTIONS: This is a closed book examination. Use of cell phones, laptops, dictionaries is not allowed.

- 1/ (20 pts) Three non-conducting spherical shells are fixed in place. Shell 1 has a uniform surface charge density $\sigma_1 = +5.0 \mu\text{C/m}^2$ on its outer surface and radius 6.0 cm; shell 2 has uniform charge density $\sigma_2 = +3.0 \mu\text{C/m}^2$ on its outer surface and radius 4.0 cm; shell 3 has uniform charge density $\sigma_3 = +2.0 \mu\text{C/m}^2$ on its outer surface and radius 2.0 cm. The center of shell 1 is at origin O. The centers of shell 2 and 3 are on the x axis, at 2 cm and 12 cm from origin O (Figure 1), respectively. In unit-vector notation, what is the net electric field at the origin O? ($k = 9.0 \times 10^9 \text{ N.m}^2/\text{C}^2$; Hint: Use the shell theorem)

- 2/ (10 pts) A proton is at the origin and an electron is on the y axis at $y = 0.5 \text{ mm}$. Find the electric dipole moment of these two particles in unit-vector notation. $\vec{P} = \vec{q} \vec{r}$

- 3/ (10 pts) Figure 2 shows a uniform electric field of $4.0 \times 10^5 \text{ N/C}$ perpendicular to the left face of a large neutral vertical conducting plate. Find the surface charge density of the left (σ_L) and right (σ_R) surfaces of the plate. ($\epsilon_0 = 8.85 \times 10^{-12} \text{ C}^2/(\text{N.m}^2)$; Hint: Use Gauss' law to explain the distribution of negative and positive charges on the left and right surfaces, then calculate the charge density on each surface)

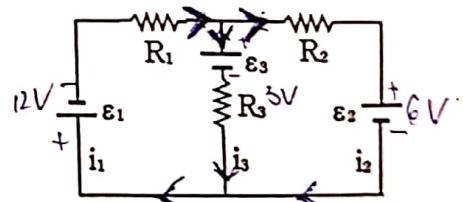

$$\mathbb{E} = \frac{\sigma}{\epsilon_0}$$

- 4/ (20 pts) Calculate the work done by an external force to bring four $2.0 \times 10^{-9} \text{ C}$ positive point charges from infinity and place them at the corners of a square of side 8 cm. ($U = \frac{kq_1 q_2}{r}$)

- 5/ (20 pts) A $25\text{-k}\Omega$ resistor and a capacitor are connected in series. A 12-V potential difference is suddenly applied across them. The potential difference across the capacitor rises to 4.0 V in $1.3 \mu\text{s}$.

Find the capacitance C. ($V = \epsilon \left(1 - e^{-\frac{t}{RC}}\right)$)

- 6/ (20 pts) Determine the currents in Figure 3 if $\epsilon_1 = 12 \text{ V}$, $\epsilon_2 = 6 \text{ V}$, $\epsilon_3 = 3 \text{ V}$, $R_1 = 1 \Omega$, $R_2 = 2 \Omega$ and $R_3 = 3 \Omega$.

END OF QUESTION PAPER

Figure 3

$$L_{\text{loop}} \quad \beta = \quad \mathcal{E}_1 =$$
